Use of Hospital Discharge Data to Monitor Uterine Rupture — Massachusetts, 1990–1997

Uterine rupture (UR), a potentially life-threatening condition for both mother and infant, occurs in <0.1% of all pregnant women and <1% of women attempting vaginal birth after cesarean section (VBAC) (*1–4*). During 1990–1997, the proportion of vaginal deliveries among women who had previous cesarean sections (CS) in Massachusetts increased 50%, from 22.3% to 33.5% (*5*). Concern about a corresponding increase in UR prompted the Massachusetts Department of Public Health and CDC to initiate a statewide investigation that included an assessment of the validity and reliability of *International Classification of Diseases, Ninth Revision, Clinical Modification* (ICD-9-CM) (*6*), codes in hospital discharge data to identify UR cases. This report summarizes the results of the investigation, which indicate that ICD-9-CM codes related to UR, designed before increased concern about UR, lack adequate specificity for UR surveillance and have not been applied consistently over time.

Using 1990–1997 state hospital discharge data, suspected UR cases were identified based on three ICD-9-CM diagnostic codes (*6*). Suspected cases were defined as women discharged from Massachusetts hospitals from 1990 through 1997 with an ICD-9-CM diagnostic code in any of the 10 diagnostic fields of 665.0 ("rupture of uterus before onset of labor"), 665.1 ("rupture of uterus during labor," including "rupture of uterus not otherwise specified"), or 674.1 ("disruption of cesarean wound," including "dehiscence or disruption of uterine wound"). Women with and without a history of CS were included. The four-digit ICD-9 codes 665.0 and 665.1 are contained within the larger three-digit category of code 665, "other obstetrical trauma," that also includes "damage from instruments." In addition, the ICD-9-CM index directs coders to use 665.1 for "laceration of the uterus, obstetrical trauma not elsewhere classifiable (NEC)," a frequent incidental complication that occurs during delivery of the fetus through the uterine incision.

To identify cases of UR, hospital medical records of suspected cases, including registration sheets, discharge summaries, and surgical reports, were obtained and reviewed by two clinicians to confirm a UR. UR was defined as any unintentional disruption of the uterine wall in a pregnant woman regardless of cause, size, degree of severity, or location and was described in the hospital chart as a rupture, dehiscence, separation, window, or rent. URs occurring in women with and without prior CS scars were included. Incidental extensions or lacerations of a uterine incision during a CS, postpartum separation of the uterine scar resulting from infection, or extremely thin lower uterine segments without disruption of the uterine wall were not considered URs. Positive predictive

Uterine Rupture — Continued

values (PPVs) were calculated as the number of confirmed cases divided by the number of reviewed suspected cases multiplied by 100. PPVs were calculated for codes 665.0 and 665.1 combined, for code 674.1, and for all three codes combined, by year and overall.

From 1990 through 1997, 1244 suspected cases were identified. Of these, 608 (48.8%) had ICD-9-CM code 665.0 or 665.1, 629 (50.5%) had code 674.1, and seven (1.0%) were coded with both 665.1 and 674.1 (Table 1). Of the 1207 (97.0%) hospital records that were reviewed, 480 (39.8%) cases were confirmed as URs. Among the confirmed cases of UR, 442 (92.1%) occurred among women with at least one previous CS, 33 (6.9%) among women with an unscarred uterus, and five (1.0%) among women who had another type of uterine scar (e.g., myomectomy).

The average PPV during the 8-year period was 50.7% for ICD-9-CM codes 665.0 and 665.1 and 28.6% for code 674.1. The overall PPV of the three codes was 39.8%. The number of suspected UR cases coded with 665.0 or 665.1 increased steadily from 1990 through 1997. However, the number of confirmed cases and PPV increased during 1990–1994, but from 1994 through 1997 the number fluctuated while PPV declined. The number of suspected and confirmed cases and the PPV of ICD-9-CM code 674.1 remained relatively stable during the same time period.

Of the 726 suspected cases confirmed as nonruptures, 694 (95.6%) of the charts contained enough information to identify a reason for the use of one of the three diagnostic codes for UR. Codes were used correctly in 81.3% of the nonrupture charts to record a condition that falls within the ICD-9-CM definitions. Among the 19.7% of records where the codes were not used correctly, 14.0% were miscoded (i.e., a condition was recorded that should have been coded with a different ICD code), 4.0% were data entry errors, and 0.6% could not be categorized because no condition mentioned in the chart appeared to be related to one of the three ICD-9-CM codes (Table 2).

Editorial Note: Administrative information, such as hospital discharge data, is often used for surveillance purposes. This study indicates that hospital discharge data alone cannot be used to monitor trends in UR because ICD-9-CM codes lack the required specificity and consistency in application. However, even though the PPV of codes 665.0 and 665.1 was higher than the PPV of code 674.1, the number of URs would have been undercounted by one third without including records with diagnostic code 674.1.

The purpose of the ICD-9 and the ICD-9-CM classification systems is to place conditions into relevant categories for statistical purposes (*6,7*). ICD-9-CM is adapted from ICD-9, which was published in 1977 before concern about rising CS rates. It was not designed to monitor UR as a complication of labor; therefore, the low overall PPVs can be explained by including other conditions in ICD-9-CM codes 665.0, 665.1, and 674.1. Reasons for the decline in the PPV of ICD-9-CM codes 665.0 and 665.1 during 1994–1997 are unclear but may represent changes in coding practices, an actual shift in clinical outcomes, or a combination of both. Coding practices may have been affected by obstetric coding guidelines issued in 1995 by CDC's National Center for Health Statistics to standardize the application of ICD-9-CM codes across facilities, and by changes in obstetric reimbursement policies that may have encouraged more extensive reporting. Clinical outcomes may have been affected by a decline in the proportion of births delivered by CS and an increase in VBACs.

International Classification of Diseases and Related Health Problems, 10th Revision (ICD-10) was published in 1992, also before increased concern about URs, and is scheduled to replace ICD-9-CM for coding of morbidity in 2005. However, ICD-10 does not

Uterine Rupture — Continued

address the lack of specificity of codes to identify UR cases accurately (*8*). Future revisions to ICD-10 and ICD-10-CM should include a code specifically for "uterine rupture associated with previous CS scar."

An alternate data source for monitoring URs will be the revised national standard certificate of live birth, scheduled to go into use in 2003. It will contain a checklist for maternal morbidity including UR. This data source will need to be validated for its sensitivity and specificity through medical records review.

VBAC generally is considered safe practice, and 75% of women attempting a VBAC are successful (*2*). However, the greatest risk factor for UR is labor among women with a previous CS. The findings in this report indicate that the number of URs increased from 1990 to 1994, with a notable increase from 1993 to 1994. This pattern is similar to the change in the proportion of VBACs among women with a previous CS. Data to estimate the frequency of VBAC attempts are unavailable; therefore, the risk for UR among women attempting VBAC is unknown.

The incidence of UR may have been higher than that reported in this study. The negative predictive value of the three diagnostic codes is unknown because the probability that persons who were not reported to have a UR were free of UR could not be ascertained. In addition, the severity of UR varies from inconsequential to catastrophic; therefore, minor cases may remain clinically undetected and unreported. The need to monitor and assess the competing risks for morbidity associated with different methods of delivery will continue to be important.

Imported Dengue — United States, 1997 and 1998

Dengue is a mosquito-transmitted acute viral disease caused by one of four dengue virus serotypes (DEN-1, DEN-2, DEN-3, and DEN-4). Dengue is endemic in most tropical areas of the world and has occurred in U.S. residents returning from travel to such areas. CDC maintains a laboratory-based passive surveillance system for imported dengue among U.S. residents. The system relies principally on reports by clinicians to state

Imported Dengue — Continued

health departments, which forward patient specimens to CDC for diagnostic testing. This report summarizes information about imported dengue cases among U.S. residents for 1997 and 1998, which indicates that most persons with a known travel history probably acquired infection in the Caribbean islands or Asia.

Serum samples from 349 persons who had suspected dengue based on clinical presentation and onset of symptoms (*1*) in 1997 and 1998 were submitted to CDC from 40 states and the District of Columbia. From these samples, 143 (38%) cases were laboratory diagnosed as dengue, 133 (93%) cases had IgM antibody in early convalescent samples or single high titers of IgG antibody in acute serum samples, and 10 (7%) cases had isolation of dengue virus. In three cases, positive by detection of anti-dengue IgM antibody, virus serotype was identified by polymerase chain reaction (PCR). Overall, DEN-4 was identified in five (39%) cases, DEN-2 in four (31%) cases, and DEN-1 and DEN-3 in two (15%) cases each (Table 1). Dengue diagnosis was negative in 129 (37%) patients and indeterminate in 77 (22%) patients because convalescent samples for serologic testing were unavailable.

Of the 143 persons with laboratory-diagnosed dengue, sex was known for 130; 65 (50%) were males. Age was reported for 99 persons and ranged from age <1–70 years (median: 34 years). States reporting the highest number of cases were Florida (12) in 1997 and New York (22) in 1998. Travel histories within the 2 weeks before illness, available for 122 persons, indicated that infections probably were acquired in the Caribbean islands (61 cases), Asia (30), Central America (23), South America (four), Africa (three), and the Pacific islands (one). In 1998, 90 laboratory-diagnosed cases were reported, a 70% increase from the 53 cases reported in 1997. Among the 90 cases, 35 (39%) persons reported traveling to the Caribbean islands in 1998 compared with 14 (26%) in 1997.

Clinical information was available for 85 patients with laboratory-diagnosed dengue. Commonly reported symptoms were fever (94%), headache (69%), myalgia (53%), rash (53%), arthralgia (32%), retro-orbital pain (27%), nausea or vomiting (25%), chills (24%), diarrhea (19%), and petechiae or ecchymoses (15%). At least seven patients were hospitalized, and one patient died (diagnosed with DEN-2 by immunohistochemistry on autopsy tissue).

Reported by: State and territorial health departments. Infectious Disease Pathology Activity, Div of Viral and Rickettsial Diseases; Dengue Br, Div of Vector-Borne Infectious Diseases, National Center for Infectious Diseases, CDC.

Editorial Note: The principal vector of dengue is the mosquito *Aedes aegypti*, which has a wide distribution in most tropical and subtropical areas. In the United States, *Ae. aegypti* can be found during summer months in many states. Most U.S. residents with dengue become infected during travel to tropical areas, although autochthonous transmission of dengue was documented in Texas in 1999 (*2,3*).

The incubation period of dengue is 4–7 days (range: 3–14 days). Dengue virus infection can be asymptomatic or cause illnesses ranging from mild undifferentiated fever to severe disease, including hemorrhagic manifestations and shock (*4*). Dengue hemorrhagic fever (DHF) is characterized by fever, minor or major bleeding phenomena, thrombocytopenia (≤100,000 platelets/mm^3), and evidence of increased vascular permeability (e.g., hemoconcentration [hematocrit increased by at least 20% from baseline], pleural or abdominal effusions, or hypoproteinemia) (*4*). Dengue shock syndrome (DSS) is DHF with signs of circulatory failure, including narrow pulse pressure (≤20 mmHg), hypotension, or shock, and may result in death rates of approximately 10% (*5*).

*Conducted active surveillance from April 1, 1997, to March 31, 1998.
[†] Polymerase chain reaction.
[§] The Texas laboratory-based surveillance system detected 16 serologically documented cases during 1997–1998, which were not included in this report; six (38%) diagnoses were based on results from commercial laboratories. Among the 16 cases, four occurred in patients who had no history of international travel.

Imported Dengue — Continued

From 1993 through 1998, the number of imported laboratory-diagnosed U.S. cases increased, reflecting the impact of travel and the occurrence of epidemic activity, especially in the Caribbean and Central America. In 1998, laboratory-diagnosed cases of dengue were more than double the number reported in 1997. This pattern is consistent with the increased number of cases of dengue/DHF in the Americas for 1998 (741,794) compared with 1997 (364,945) (*6*).

The findings in this report are subject to at least two limitations. First, the number of dengue cases referred to CDC for diagnosis represents a minimum estimate of the actual number of U.S. travelers with dengue fever or its complication, DHF or DSS. Because dengue is not a nationally notifiable disease, diagnostic samples may not be sent for testing or may be sent to laboratories other than CDC; therefore, many imported cases may not be counted. For example, Florida implemented an active laboratory-based surveillance system from April 1, 1997, through March 31, 1998, which resulted in an increased detection of laboratory-positive cases from a previous 30-year annual mean of 1.4 cases to 18 cases during this period (*7*); five of the 18 cases were reported from private clinical laboratories. Second, travel histories and clinical information were not available for all persons with dengue, and they may not be representative of all persons with imported dengue.

Persons traveling to areas where dengue is endemic should avoid exposure to mosquitoes by using repellents, wearing protective clothing, and remaining in well-screened or air-conditioned areas. No vaccine is available for preventing dengue infection. The *Ae. aegypti* mosquito is well adapted to urban environments and can be found in or near human dwellings, where the mosquito can be found in closets, bathrooms, behind curtains, and under beds. The species usually bites during the early morning and late afternoon, but may feed at any time during the day when indoors or during overcast periods (*8*).

With an increase in traveling to and from endemic areas, more cases of imported dengue may be expected and health-care providers should consider dengue in the differential diagnosis of illness for all patients who have fever and a history of travel to tropical areas within 2 weeks before the onset of symptoms. Supportive measures should be given, and only acetaminophen is recommended for management of pain and fever. Acetylsalicylic acid (i.e., aspirin) and other nonsteroidal anti-inflammatory agents are contraindicated because of their anticoagulant properties. Acute-phase and convalescent-phase serum samples should be obtained for viral isolation and diagnosis and sent for confirmation through state or territorial health departments to CDC's Dengue Branch, Division of Vector-Borne Infectious Diseases, National Center for Infectious Diseases, 2 Calle Casia, San Juan, PR 00921–3200; telephone (787) 766-5181; fax (787) 766-6596. Serum samples should be accompanied by a summary of clinical and epidemiologic information, including date of onset of disease, date of collection of sample, and a detailed recent travel history.

Progress Toward Poliomyelitis Eradication — Democratic Republic of Congo, 1996–1999

In 1988, the World Health Assembly resolved to eradicate poliomyelitis by December 31, 2000 (*1*). Although progress has been extraordinary (*2*), full implementation of polio eradication strategies has been delayed in several countries affected by war. The Democratic Republic of Congo (DRC) has experienced continual armed conflict since October 1996. As a result, DRC is the last country in the African Region of the World Health Organization (WHO) to implement National Immunization Days (NIDs*). DRC is an important global reservoir for wild poliovirus and shares more than 5580 miles (9000 km) of border with nine countries†; in at least seven of these countries polio is endemic. The large area of DRC, substantial amount of poverty, weak health-care infrastructure, poor transportation and communication, and competing demands for resources present considerable challenges to polio eradication. This report summarizes information on the existing health-care infrastructure and routine coverage, information from NIDs carried out in 1999, and results from the recently established surveillance system for acute flaccid paralysis (AFP).

Existing Health-Care Infrastructure and Routine Vaccination Coverage

DRC has an estimated population of 48.7 million persons§; 70% live in rural areas. As a result of armed conflict, health-care administration and logistics have become divided into two operational sectors. The western sector receives vaccine, cold chain equipment, and other supplies through Kinshasa while the eastern sector is supplied through Goma. The Ministry of Health (MOH) is supported by WHO, the United Nations Children's Fund (UNICEF), and national and international nongovernment organizations. In DRC during 1984–1995, mortality in infants (127 per 1000) and children aged <5 years (205 per 1000) remained static. Life expectancy is 45 years, and the maternal mortality rate is among the highest in the world (870 per 100,000 births).

Expanded Program on Immunization (EPI) activities are coordinated by 42 subprovincial offices; each is headed by an EPI office and comprises several of the

*Nationwide mass campaigns over a short period (days to weeks), in which two doses of oral poliovirus vaccine are administered to all children in the target age group (usually aged <5 years), regardless of vaccination history, with an interval of 4–6 weeks between doses.
† Angola, Burundi, Central African Republic, Congo, Rwanda, Sudan, Tanzania, Uganda, and Zambia.
§ Based on the results of the 1999 NIDs.

Poliomyelitis Eradication — Continued

307 health zones. Coverage in the western sector with three doses of oral poliovirus vaccine (OPV3) among children aged <1 year was an estimated 20%. Coverage with OPV3 in the eastern sector of North Kivu was 36% for the first 6 months of 1999. No data are available for the other eastern sector provinces where coverage is estimated to be lower. In 1998, a survey estimated 59% OPV3 coverage nationwide among children aged 12–23 months. Except for Angola (*3*), DRC is the only other African country where large outbreaks have been reported since polio eradication activities began in Africa in 1996. In 1995, approximately 1000 polio cases were reported in Mbuji May (Kasai Oriental). In 1997, 30 cases (and three deaths) were reported in Walikale (North Kivu), and 25 cases (no deaths) were reported in Inongo (Bandundu). In 1998, 87 cases (14 deaths) were reported in Walikale and seven cases (three deaths) in Kiri (Bandundu).

National Immunization Days

During January–October 1996, Local Immunization Days (LIDs) were conducted in DRC's 32 most populous cities; 1,134,416 children aged 0–59 months (89% of the target population) received two doses of OPV. In 1997, LIDs were carried out in the 47 most populous cities and in 98 health zones along the eastern border. Reported coverage was 97% for Kinshasa and 80%–85% for other cities. In August 1998, the first NIDs were disrupted by the resumption of war. Although hostilities made nationwide implementation impossible, subnational NIDs were conducted in five of the country's 11 provinces; 3.4 million children (92% of the target population) were vaccinated with OPV. In 1999, three rounds of NIDs were planned for August, September, and October. The United Nations General Secretary arranged a cease-fire between the DRC government and the main opposing forces, and urged all factions to observe days of tranquility during NIDs. Vitamin A supplementation (*4*) was added to the second round of NIDs and measles vaccination to the third round in selected health zones. Because war created difficulty of movement between the eastern and western sectors, a team based in Goma planned and supervised NIDs for the eastern sector while the Kinshasa-based team planned and monitored NIDs for the western sector. Supplies for the east and west came through Goma and Kinshasa, respectively.

Of the country's 307 health zones, 298 (97%) developed a plan to implement NIDs, and these plans were integrated into the overall national plan. Despite the agreement, on August 13, the first NIDs round, targeting all children aged 0–59 months, was disrupted by renewed fighting in the eastern sector; however, 80,000 health-care workers vaccinated in 11 provinces and 298 (97%) health zones were reached (Table 1). In nine health zones, no vaccination activity occurred; only one round was conducted in three zones (1%); 47 (15%) health zones conducted only two rounds. This accounts for the disparities in the numbers of children vaccinated in each round in some provinces (Table 1); 71%, 86%, and 81% of children in the target age group received OPV in the first, second, and third round, respectively; 6,098,500 (67%) children aged 6–59 months received a supplemental dose of vitamin A during the second round, and 3,321,832 children aged 9–59 months (80% of those targeted) were vaccinated against measles.

AFP Surveillance

In early 1999, AFP surveillance was initiated throughout DRC. The chief medical officers of each health zone are responsible for AFP surveillance and are supported by provincial EPI coordinators who report to the national EPI coordinator. Seven WHO suboffices created in 1995 provide MOH with logistic and technical assistance for AFP

TABLE 1. Number of children aged 0–59 months*, number receiving oral poliovirus vaccine (OPV) during National Immunization Days† (NIDs), number of reported cases of acute flaccid paralysis (AFP), and nonpolio AFP rates, by province — Democratic Republic of Congo, 1999

	NIDs				AFP surveillance			
		No. children vaccinated

Poliomyelitis Eradication — Continued

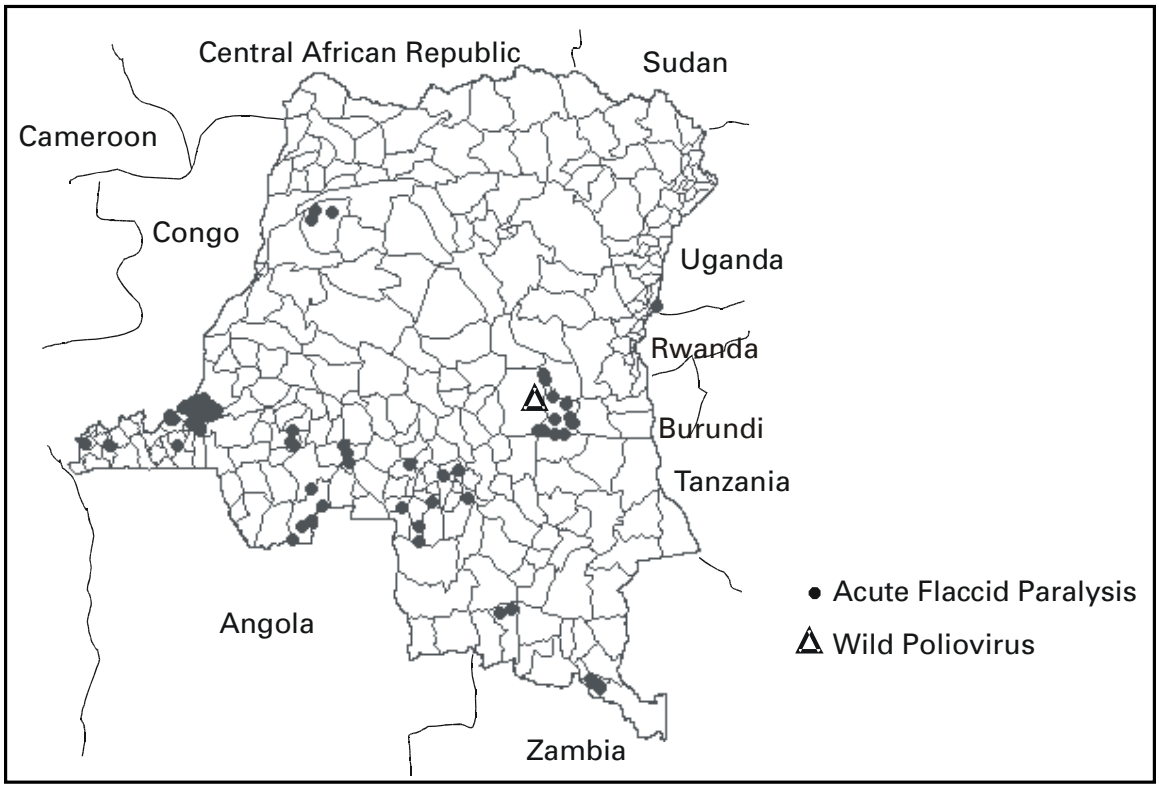
surveillance activities. Although medical personnel have been trained in AFP surveillance in all provinces, surveillance is largely passive (there is no zero-case reporting from health facilities). From each of the 11 provinces, one national surveillance officer is recruited and provided with transportation. The National Institute for Biomedical Research was identified as the national polio reference laboratory and obtained WHO accreditation in December 1999.

During 1999, 85 AFP cases were reported (Figure 1). All 85 had at least one stool specimen collected. Adequate¶ stool specimens were collected from 44 case-patients; 43 were negative for wild poliovirus and were classified as nonpolio. In 1999, three rounds of NIDs were planned for August, September, and October. Wild poliovirus type 3 was isolated from a stool specimen taken 30 days after onset of paralysis from a case-patient in Mbuji May (Kasai Oriental). Sixty-day follow-up examinations were not conducted for the 41 cases with inadequate specimens, which were confirmed as polio on clinical case classification criteria**. The overall nonpolio AFP rate was 0.17 per 100,000 children aged <15 years.

¶ Two stool specimens collected at an interval of at least 24 hours within 14 days of paralysis onset.

** AFP cases are confirmed as polio if wild poliovirus is isolated from two specimens, if follow-up examinations 60 days after onset show residual paralysis, or if no follow-up could be conducted (i.e., patient died or was lost to follow-up).

FIGURE 1. Acute flaccid paralysis (AFP) and wild poliovirus cases, by district — Democratic Republic of Congo, 1999



Poliomyelitis Eradication — Continued

Reported by: World Health Organization (WHO) Country Office, Kinshasa, Democratic Republic of Congo (DRC); United Nations Children's Fund (UNICEF) Country Program, Kinshasa, DRC. Regional Office for Africa, WHO, Harare, Zimbabwe. Regional UNICEF Office for West and Central Africa Region, Abidjan, Côte d'Ivoire. UNICEF, New York. Vaccines and Biologicals Dept, WHO, Geneva, Switzerland. Respiratory and Enteric Viruses Br, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases; Vaccine Preventable Disease Eradication Div, National Immunization Program, CDC.

Editorial Note: The goal of global polio eradication will not be achieved unless strategies are implemented effectively in all countries where polio is endemic, including those affected by civil unrest or war. This report from DRC, together with reports from Afghanistan (*5*), Somalia, southern Sudan (*6*), and other war-torn areas (*7*), suggests that even under extremely adverse conditions, effective polio eradication strategies can be implemented.

NIDs in DRC that reached almost all health zones and the initiation of AFP surveillance demonstrate that armed conflict does not present an insurmountable barrier to implementing eradication strategies. Despite the successes, however, future NIDs must cover all areas of the country. Nine health zones, with a combined target population of 270,000 children aged <5 years, were not reached during the 1999 NIDs; conflict prevented another 57 health zones from completing OPV3 rounds.

In 2000, a cease-fire, days of tranquility for NIDs respected by all armed groups, and completion of three NIDs rounds in all 307 DRC health zones are factors critical to eradication efforts. Plans for polio eradication in DRC in 2000 include strengthening routine EPI; conducting three rounds of intensified NIDs in July, August, and September 2000 (including house-to-house vaccination in much of the country); and expanding AFP surveillance. The long-term success of NIDs in DRC requires the negotiation of a formal cease-fire; the strong commitment of the DRC government; a solid partnership between MOH, United Nations agencies, and other organizations; commitment of the necessary funds and resources to overcome the limitations of the existing infrastructure; and a decentralized approach to planning and implementation.

The detection of 85 AFP cases also demonstrates that AFP surveillance can be initiated in countries affected by war and limited infrastructure. Cases already have been reported from nine of the country's 11 provinces. The success is primarily the result of MOH commitment and the establishment of a surveillance infrastructure. The sensitivity, quality, and geographic extent of AFP surveillance must be enhanced to ensure that data can be used to target mopping-up activities as polio transmission becomes focused in DRC. Active surveillance with zero-case reporting from the main referral hospitals must be initiated. If DRC is to eradicate polio by the end of 2000, the necessary human, material, and financial resources must be made available in a timely manner[††]. International, national, and local efforts pressing for peace or at least access to children for vaccination and other health activities must be a priority.

Public Opinion About Public Health — United States, 1999

Previous surveys have documented a substantial gap in the public's understanding and attitudes about public health (*1*). The Pew Charitable Trusts, a Philadelphia-based philanthropy that supports nonprofit activities in the areas of culture, education, the environment, health and human services, public policy, and religion, commissioned two firms, the Mellman Group and Public Opinion Strategies, to conduct both qualitative and quantitative research in 1999 to characterize the public's attitudes about public health. In particular, the Pew Charitable Trusts asked the groups to explore 1) perceptions about public health in general, including levels of support and importance compared with other national priorities; 2) opinions about environmental health and its role in causing disease and promoting health; and 3) opinions about the public health infrastructure. This report summarizes the results of this survey, which indicate that the term "public health" is misunderstood, persons are concerned about the quality of the public health system, increased government spending for public health is a greater priority than other key national concerns, and that the public regard environmental factors as important contributors to certain health problems.

During March 24–31, 1999, the groups conducted a national telephone survey of 1234 registered voters. Registered voters, selected by random-digit–dialing, were chosen because of their potential influence on setting government priorities. Respondents were first asked to respond to a series of statements defining public health. Respondents were then given a definition of public health (i.e., protecting the population from disease) and asked a series of questions about federal resources devoted to public health and other programs. Respondents also were asked about their beliefs on the links between environmental factors and disease. The sampling margin of error was ±2.8% at the 95% confidence level.

Respondents were asked "When you hear the term 'public health,' what do you think of?" and then given a choice of four descriptions. Approximately half (57%) of the respondents could not define public health as either protecting the population from disease or policies and programs that promote healthy living conditions for everyone.

Interviewers then defined public health and asked respondents to rate (i.e., excellent, good, fair, or poor) the current system for protecting public health. Most (57%) respondents offered negative evaluations of the public health system. Respondents also were asked whether sufficient resources were being dedicated to public health; 65% said that the United States should do more to protect public health. When asked to compare public health as a spending priority with several other key programs, most said public health was more deserving of additional funds than building roads and highways (80%), missile defense (73%), and cutting taxes (63%). Only education was viewed as a greater priority for additional resources (24%).

Public Opinion — Continued

When asked about environmental factors (e.g., pollution) and their relation to public health, 85% said they believed that environmental factors are important determinants of disease and health problems. Of these, 38% considered environmental factors very important.

Respondents were asked to indicate how much impact environmental problems have on the public health. Most respondents believed that environmental factors play an important role in causing certain diseases. Sinus and allergy problems (54%), childhood asthma (54%), childhood cancer (39%), colds and influenza (35%), and birth defects (36%) were the health problems seen as most likely resulting from environmental factors (Table 1).

Respondents were given nine environmental issues and asked what impact each had on the population's health (a great deal, some, not too much, not at all, or don't know). Contaminated drinking water (58%), toxic waste (56%), air pollution (53%), foods contaminated with bacteria (53%), and pesticides in foods (47%) were considered to have the greatest impact (Table 2).

Reported by: SA Hearne, DrPH, PA Locke, DrPH, Pew Environmental Health Commission, Johns Hopkins School of Public Health, Baltimore, Maryland. M Mellman, P Loeb, L Dropkin, Mellman Group; G Bolger, N Fink, Public Opinion Strategies, Washington, DC. M Byrnes, MPA, Pew Charitable Trusts, Philadelphia, Pennsylvania.

Editorial Note: Societal support is critical for public health efforts, which target population-based disease prevention and collective action. Since 1981, financial support for public health infrastructure has decreased (*2,3*), and national expenditures for health-care services have increased (*4,5*). The diminishing resources for public health combined with the increasing costs of medical intervention may indicate a failure to communicate the efficacy of public health practices and programs.

The findings in this report are subject to at least two limitations. First, the survey design defined public health but not the public health system. Second, spending priorities do not necessarily address support of specific public health initiatives. The survey does indicate substantial support for public health when the public understands the concept, which has important implications for how public health professionals communicate with the public, policymakers, and the media.

TABLE 1. Percentage of participants' responses to the level of impact of environmental factors on selected health problems — Pew Charitable Trusts Public Health Survey, United States, 1999

Health problem	Very important	Somewhat important	Not too important	Not at all	Don't know
Sinus problems/allergies	54%	35%	24%	22%	24%
Asthma in children	54%	35%	4%	3%	5%
Colds/Influenza	35%	41%	11%	10%	3%
Childhood cancer	39%	35%	8%	8%	10%
Birth defects	36%	37%	9%	7%	10%
Breast cancer	28%	33%	15%	13%	12%
Brain tumors	24%	32%	12%	14%	18%
Infertility	20%	36%	15%	14%	16%
Learning disabilities	21%	29%	21%	19%	11%
Prostate cancer	20%	29%	17%	17%	17%
Behavioral disorders	18%	28%	21%	21%	12%
Childhood injury	15%	24%	23%	29%	10%

Public Opinion — Continued

TABLE 2. Percentage of participants' responses to the level of impact the environment has on a person's health, by environmental problem — Pew Charitable Trusts Public Health Survey, United States, 1999

Problem	Great deal	Some	Not much	Not at all	Don't know
Air pollution	53%	38%	25%	22%	22%
Sick buildings	26%	36%	10%	5%	22%
Contaminated drinking water	58%	28%	8%	3%	3%
Food contaminated with bacteria	53%	34%	9%	2%	1%
Pesticides in foods	47%	36%	10%	4%	3%
Toxic waste	56%	29%	9%	2%	5%
Chemicals in consumer products	35%	42%	15%	5%	3%
Depletion of ozone layer	36%	33%	12%	9%	10%
Electromagnetic fields created by power lines	19%	32%	17%	16%	17%

The findings in the survey indicate that most registered voters believe the environment is an important determinant in maintaining good health. The identification of environmental health issues with public health may enable public health professionals to better inform the public about the importance of a population-based focus on disease prevention.

Alternate Two-Dose Hepatitis B Vaccination Schedule for Adolescents Aged 11–15 Years

In September 1999, Merck Vaccine Division (Merck & Co., Inc., West Point, Pennsylvania*) received approval from the Food and Drug Administration for an optional two-dose schedule of Recombivax HB® for vaccination of adolescents aged 11–15 years. The Advisory Committee on Immunization Practices approved the optional two-dose schedule in October 1999 and recommended to include this schedule in the Vaccines for Children Program in February 2000. Using the two-dose schedule, the adult dose of Recombivax HB® (1.0 mL dose containing 10 µg of hepatitis B surface antigen [HBsAg]) is administered to adolescents aged 11–15 years, with the second dose given 4–6 months after the first dose. In immunogenicity studies among adolescents aged 11–15 years, antibody concentrations and end seroprotection rates (≥10 milli-international units per mL of antibody to HBsAg) were similar with the two-dose schedule (1.0 mL dose containing 10 µg of HBsAg) and the currently licensed three-dose schedule (0.5 mL dose containing 5 µg of HBsAg). The overall frequency of adverse events was similar for the two-dose schedule and the three-dose schedule. Short-term (2-year) follow-up data indicate that the rate of decline in antibody levels for the two-dose schedule was similar to that for the three-dose schedule. No data are available to assess long-term protection (beyond 2 years) or immune memory following vaccination with the two-dose schedule, and it is not known whether booster doses of vaccine will be required. As with other hepatitis B vaccination schedules, if administration of the two-dose schedule is interrupted it is not necessary to restart the series. Children and adolescents who have begun vaccination with a dose of 5 µg of Recombivax HB® should complete the three-dose series with this dose. If it is not clear which dose an adolescent was administered at the start of a series, the series should be completed with the three-dose schedule.

Injury-Related Mortality Reports Database Available on Internet

WISQARS™ (Web-based Injury Statistics Query and Reporting System), pronounced "whiskers," is an interactive system that provides injury-related mortality data useful for research and for making informed public health decisions. Mortality data for 1981–1997 are produced in two report formats: 1) Injury Mortality Reports, which can be used to determine injury deaths and death rates for specific external causes of injuries, and 2) Leading Causes of Death Reports, which can be used to determine the number of injury-related deaths relative to the number of other leading causes of death in the United States or in individual states. The report is available at http://www.cdc.gov/ncipc/wisqars.

Notices to Readers — Continued

Both reports are available by year, age, race, sex, Hispanic origin, and state. Reports can be requested by 5-year age ranges (e.g., 0–4 years or 5–9 years) or a custom-defined range (e.g., 13–19 years or all 6-year-olds only). Race categories are white, black, American Indian/Alaskan Native, Asian and Pacific Islander, and other (all nonwhite and nonblack and may include other races not listed). In addition, Injury Mortality Reports can be requested by these specific definitions and other parameters (e.g., a report for a mechanism/cause and manner/intent in a specific state by sex and race).

National Vaccine Program Office Workshop on Aluminum in Vaccines

CDC's National Vaccine Program Office will sponsor Workshop on Aluminum in Vaccines during May 11–12, 2000. The workshop will be held at the Caribe Hotel in San Juan, Puerto Rico, immediately following the Metal Ions in Biology and Medicine Conference. Discussion topics include vaccine adjuvants, aluminum salts in vaccines, the pharmacology and toxicology of aluminum, and macrophagic myofascitis. Additional information is available on the World-Wide Web at http://www.cdc.gov/od/nvpo/calendar, or telephone (404) 687-6672.

Erratum: Vol. 49, No. SS-1

In the *MMWR Surveillance Summaries*, "Surveillance for Foodborne-Disease Outbreaks—United States, 1993–1997," Table B has two errors on page 61. In the *Cryptosporidium parvum* section, under Confirmation, the second option should read "Demonstration of organism in epidemiologically implicated food." In the following section, the agent listed should be "*Cyclospora cayatenensis*."

U: Unavailable -:no reported cases

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

†Pneumonia and influenza.

§Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

¶Total includes unknown ages.

Kathryn Snavely

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/* or from CDC's file transfer protocol server at *ftp.cdc.gov*. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to: Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.
